ABSTRACT

In the present scenario welding of dissimilar metals is very important because one metal cannot give optimum chemical, physical and mechanical properties required for an application. Like Al-Steel or Mg-Al welding for reducing the weight of the transportation vehicles such as train, automobile, and ship, high alloy material-low alloy steel or stainless steel- low carbon steel for strength and corrosion resistance, Al-Cu for electronic components. So many researches have been carried out on joining of Fe-Al by RSW using different elements as interlayer but optimization of cladding ratio for transition material is not done. Here in this paper condition for optimum performance is determined in the terms of influence of parameters on the tensile shear strength of the weld, optimize the process parameters without the Silver interlayer, optimize the process parameters with the Silver interlayer, and investigate the mode of failure of these welds.

Keywords: Resistance Spot Welding, Shear Strength, Cladding Ratio, Transition Material.

I. INTRODUCTION

Resistance spot welding (RSW) is a productive joining process. It is broadly utilized for the creation of sheet metal assemblies. RSW has excellent techno-economic advantages like high speed, low cost and suitability for automation.

1.1 Resistance spot welding for dissimilar metal joints

Resistance welding for dissimilar metal weld required proper heat balance. Heat balance plays a very important in dissimilar metal welding to obtain the good quality weld. As different metal have different properties like thermal conductivity, electrical conductivity, thermal coefficient of expansion and contraction. Due to that heat generation and heat lose will be different for different metal. Proper heat balance is done by several methods depend upon the situation. If we are welding two dissimilar metal and sheet having equal thickness then we can do the heat balance by adjusting the contact area of electrode and sheet interface.

Fig. 1 Heat balance at different situations [19]
A- Electrode with smaller face area used for high-conductivity alloy.
B- High electrical resistance electrode used for high conductivity alloy.
C- Same as B with addition of larger electrode face used for low conductivity material.
D- Increase thickness of high conductivity work piece.

One other problem with dissimilar metal joining is that of plasticity temperature range of metals. If plasticity temperature range of two metals is largely differing, then they are difficult to weld. One of the major problems of dissimilar metal joining is formation of brittle intermetallic compounds. As they are brittle in nature due to which strength of the joint reduced.

II. LITERATURE REVIEW

The joining of Al-Fe is not an easy task. There welding is tough due the having lot of difference in the properties like melting point temperature, coefficient of thermal expansion and contraction, thermal conductivity, electrical resistivity. The one of the major problem is formation of brittle intermetallic compound layer at the interface.

According to Seyedeh Nooshin Mortazaviet al. [1] who has perform an experiment on low carbon steel and A52500 aluminium alloy by using RSW, there is formation a brittle intermetallic layer who deteriorate the tensile strength of the weld. The formation of intermetallic compound layer is due to limited solubility of Iron in Aluminium and vice versa. Only small amounts of iron can be dissolved in aluminium, and only small amounts of aluminium can be dissolved in iron. Iron and aluminium form various intermetallic phases of low strength and low toughness. The intermetallic compounds "which are available on it" are gathered as Fe-rich mixes (FeAl and Fe3Al) and Al-rich mixes (FeAl2, Fe2Al5, and FeAl3). Along with these stable compounds, metastable compounds (FeAl6, Fe2Al9, and FeAl8) have been also form in Al/steel interface.

According to W.H. ZHANG et al. [7] who has performed an experiment on H220 Zn-coated high strength steel and 6008 aluminium alloy by RSW find that the intermetallic compound layer at steel/aluminium interface in resistance spot welded joint of H220 Zn-coated high strength steel and 6008 aluminium alloy was mainly composed of η-Fe2Al5 and θ -FeAl3 phases, and the morphology and thickness of the intermetallic compound layer varied with the locations along the interface in the weld. The formation and growth of the intermetallic compounds (η-Fe2Al5 and θ -FeAl3) were controlled by reactive diffusion between solid steel and liquid aluminium alloy during resistance spot welding.

Resistance spot welding with interlayer a study done by Zhang et al. [8] on the H220YD0 galvanised high strength steel to 6008 aluminium alloy by Intermediate frequency RSW using a Alsi12 interlayer at the interface of steel and aluminium. They have found that thickness of intermetallic compound layer is decreasing by the application of inter layer. Due to that strength of the weld is increased considerable as compare to other methods. Eggeler et al. [9] found that Si can reduce the formation and growth of intermetallic layer in the Iron aluminium joining. As we know that from the above discussion that Fe2Al5 and FeAl3 type compound are form in the reaction layer or in intermetallic compound layer of Fe and Al [8]. First FeAl3 type compound is generated at the interface and after that Fe2Al5 type of compound is formed by the diffusion of Al atom to the solid aluminium through the FeAl3. As Fe2Al5 have a orthorhombic structure, when we used Si in the interlayer the Si atoms are then fitted into the vacancies of Fe2Al5 in the e-direction and reduced the diffusion of Al atoms in to that. Due to this reason thickness of

2.1 Gaps in Literature Review

After doing the detail study of the literature, the following gaps are found:

1. Few literatures are available on joining of Fe-Al by RSW using different elements as interlayer.
2. In the literature cladding ratio optimization for transition material is not clear.
3. In the joining of Fe-Al by using 4047 AlSi12 interlayer the effect of electrode force and weld time is not explained properly.
4. Joining of Fe-Al by using interlayer with the cover plate has not been tried.
5. Different materials (Ti, Ag, Cu, Ca, Mg) as interlayer has not been used.

2.2 Objective of this research

1. To study the influence of parameters on the tensile shear strength of the weld.
2. To optimize the process parameters without the Silver interlayer
3. To optimize the process parameters with the Silver interlayer.

4. To investigate the mode of failure of these welds.

III. METHODOLOGY

3.1 Material selection

A 1.0 mm thick Stainless steel (304) sheet with yield strength and ultimate tensile strength of 215 and 505 MPa, and 1.5 mm thick aluminium (A5052) sheet with yield strength and ultimate tensile strength of 89.6 and 193 MPa was used in the research work. A Silver interlayer of 100µm thickness was also used. The thickness of stainless steel sheet was taken different due to the heat balance during welding.

3.2 Welding Machine

Spot welding was performed using a 150KVA AC Pedestal type Resistance Spot Welding Machine. Welding was done using a 45° truncated cone RWMA class 2 electrode. The face diameter of Electrode was 10mm as shown in fig 3.1. The Electrode was made by tapper turning on the lath machine.

3.3 Sample Preparation

Static tensile shear test samples were prepared according to ANSI/AWS/SAE/D8.9-97 standard [Fig. 3]. The samples were prepared with the help of shearing Machine. Firstly samples were polished up to 1200 grit size and then cleaning was done by acetone. Fig 3.3 shows the sample before the cleaning and Fig. 4 shows the sample after the cleaning.

3.4 Welding Parameters

Taguchi technique involves five steps these are as follows:

1. Find out the best parameters which affect the shear strength.

2. Design the Experiment according to partial/ full fraction design.

3. Conducts the experiments.

4. Analyse the results with the ANOVA to determine the optimum conductions and significant parameter.

5. Run a confirmatory test using the optimum conditions.

Same array was used for the spot welding with silver interlayer and the comparisons have been done between them.

Fig. 6 Sample after weld
3.5 Metallography Preparation

Metallography observation was performed on the cross section structure of the weld zone. For this weld was cut from the centre and then cross section was polished up to 2000 grit size. After that cloth polishing with MgO powder. The etchant for steel was aqua regia and for aluminium was Keller’s etchant. (190ml Distilled Water, 5ml Nitric Acid, 3ml Hydrochloric Acid, and 2ml Hydrofluoric Acid). The etching time was 12 second for aluminium and 1.5 minute for steel. After etching FESEM, EDX and stereoscopy were performed.

3.6 Shear Strength Testing

Shear strength testing was performed on the Universal Testing Machine.

3.7 Metallographic Observation

Metallographic Observation was performed by using the Stereoscopic microscope, Scanning Electron Microscope and FE-SEM.

3.8 X-Ray Diffraction

XRD of fracture surface was performed to know the type of intermetallic formed at the interface of the joint.

V. CONCLUSIONS

On the basis of the experimentation and results acquired through analysis of Tensile Shear testing, Metallographic observations, Nugget diameter, EDX, and XRD of fractured surfaces the following can be concluded:

- Welding of Steel and Aluminium is a challenging task. These welds show lower tensile shear strength due to formation of intermetallic compounds at the interface of the weld which are brittle in nature like FeAl$_3$, Fe$_2$Al$_5$.
- Welding current has the maximum effect on shear strength of the weld joint.
- Welding of SS304 with Aluminium 5052 using Silver as an interlayer, Silver reduces the formation of Fe-Al based intermetallic and replace it with Al-Ag based intermetallic, such as Ag$_2$Fe, Ag$_2$Al, which are ductile in nature.
- FESEM micrographs shows a mix mode of fracture.
- Welding of SS304 with Aluminium 5052 without using Silver interlayer shows maximum tensile shear strength 4.2 kN.
- Welding of SS304 with Aluminium 5052 using Silver as an interlayer shows maximum tensile shear strength 4.6 kN which is higher than welding without Silver interlayer.
- The EDX results support the presence of Silver at the weld interface.
- In the XRD analysis, mainly FeAl$_2$, FeAl$_3$, Fe$_2$Al$_5$ intermetallic compound and Ag$_2$Al, Ag$_3$Fe$_2$ ductile phases of Al-Ag and Fe-Ag are found.
