ABSTRACT

The rapid growth of technology in the last two decades has been characterized by full automation. As only the affluent and developed countries can afford to adopt full automation, a large productivity gap has been created. This gap can be bridged through low cost automation. The concept and principles of low cost automation are basically the same as those of full automation except that the former builds improvement around existing equipment and machine system rather than replacing whole system with automated processes. Material handling is the primary activity of every manufacturing organization. It has been estimated that at least 15 to 25% of the cost of the product is attributable to material handling activities. Unlike many other operations, material handling adds to the cost of the product and not to its value. It is therefore important first to eliminate or at least minimize the need for material handling and second to minimize the cost of handling.

Karakuri mechanisms use a single force or motion to simultaneously perform multiple operations, and also lead directly to energy conservation and resource (facilities) savings. Conventionally gravity conveyors are used to perform material handling task but they are more often of fixed layout type with a singular application. The proposed linear gravity conveyor for flexible manufacture system uses the principle of Converting the force from a dropped weight into gear rotation to activate a conveyor thereby saving the cost of motor and electricity. Conveyors are ordinarily activated by using drive from a motor. In this example, when the conveyor is lifted with a cylinder, a weight drops from the top portion of the conveyor. The force of dropped weight rotates gears that provide movement needed for slide delivery of work (semi-finished products). This mechanism eliminates the need for a motor and enabled a reduction in standby electricity and electricity for operation. Slide delivery requires only the necessary amount of driving energy at the time when needed and is therefore consistent with the concept of “just-in-time” electricity.

Objective of project is carry out critical analysis as to time-motion and economics of the developed conveyor system with linear and rotary conveyor to determine the i) Transfer time ii) Maximum load carrying capacity. Comparative analysis of the performance of the developed system with conventional conveyor to derive: Change in job transfer time.

Problem Statement:

a) Linear Conveyor

The present Linear Gravity conveyor is fixed type that is fixed length, fixed weight carrying capacity, high running cost, high power consumption & not suitable to be used with multiple machines due to rigid &
heavy mountings, fixed length & weight parameters & also not suitable to flexible manufacturing system.

This means that there conveyer is to be powered by gravity action so that there will be no running cost.

c) Conveyor weight carrying capacity should be made such that the conveyor system will automatically adjust the slide angle using a comparator and hydraulic dashpot mechanism to ensure that the job does not fall out of tray due to momentum of job at end of stroke.

2. Literature Review

Analysis and Optimization of Gravity Roller Conveyor Using Ansys [1]. The main objective of this study is to explore the analysis of Gravity roller conveyor. This has entailed performing a detailed Study of existing Gravity Roller Conveyor system and optimizes the critical part like roller, C-channel etc. by using composite material, so to minimize the overall weight of the assembly without hampering its structural strength. A proper Finite Element Model is developed using Cad software Pro/E Wildfire 5. Results of Static, Modal and Transient analysis of existing design and optimized design are compared. The material used for roller and C-channel frame is a composite material i.e. carbon fiber.

Study and Performance of Belt Conveyor System with Different Type Parameter [2].

Material handling equipment are designed for many advantage such as easy, cheap, fast and safe loading and unloading condition. Belt conveyor systems are design for easy handling of materials in terms of weigh: and height. This paper discusses the design and considerations of belt conveyor system for sample weight, in terms of size, length, capacity and speed, roller diameter, location and arrangement of pulley, angle and axis of rotation, control mode, intended application, product to be handled.

Gravity Flow Rack’s Material Handling System for Just-In-Time (JIT) Production [3].

This paper presents a review on the actual implementation of a GFR system at an automotive component’s assembly line in an accord to improve its existing MH system. The main purpose of this implementation is to reduce the material transfer activities while reducing the occupied space; hence reducing the overall production cycle time (CT). The implementation outcomes show push or gravity conveyors are ideal for significance improvement on the moving parts between workstations. Their
productivity and not to mention the minimum complexity makes them easy to material handling’s time. Service and minimizes down time.

3. Scope of Work & Objective:

a) Scope of Work

In today’s manufacturing environment, assembly work is routinely characterized by short production cycles and constantly diminishing batch sizes, while the variety of product types and models continues to increase. Constant pressure to shorten lead times adds to these demands and makes the mix truly challenging, even for the most innovative manufacturers.

1. The ability to respond quickly to rapidly changing customer demands requires the use of manufacturing systems that can be re-configured and expanded on the fly, and which can accommodate advances in assembly techniques without making any initial manufacturing investments obsolete. Although very heavy parts may be transported on belt conveyors, manual motion with objective to need and feasibility of implementation of low cost automation in material handling system.

2. Critical study of time, distance and motion study after implementation of linear rotary gravity conveyor system to present layout to determine the reduction in time, distance movement and machine downtime to derive the savings after implementation of the system.

3. Critical study of maximum load carrying capacity after implementation of linear rotary gravity conveyor system to present layout to determine the load carrying capacity after implementation of the system.

4. Comparative analysis of the linear gravity and rotary gravity conveyor systems with conventional method of material transfer to prove the effectiveness of new system over conventional or existing system.

4. Methodology of Project:

Primary work will be to do time and motion study for pilot study where in the targets of motion will be as follows:

Linear distance covered is 1m

Rotary distance covered is 1.5 m

Net distance travelled is 2.5 m

The system will be studied and tested as per below:

1) System design as to the number of components required, their sizes as per machine layout conditions
2) Selection of following parts:
3) Linear conveyor system components
4) Shock arresting machine at the end of stroke for linear conveyor
5) Rotary conveyor system components
6) Shock arresting machine at the end of stroke for Rotary conveyor

A) Manufacturing of Set-Up

1) Manufacturing of linear conveyor system
2) Manufacturing of Rotary conveyor system
3) Fabrication of combined set up to integrate both work motions to get net effect of conveyance

5. Testing Of the Linear Conveyor For Following Parameters

Observations for Angle of inclination 8 degree incline

Theoretical Derivation of the Time Required For Job to Move:

Acceleration an on an inclined plane (with friction)
Determine the rate of deceleration of 7.0 kg block sliding up an inclined angle at 35° to the horizontal. Assume that the coefficient of friction is 0.45,

Step I: Free body diagram
Step II: Calculate the component of any forces acting up or down the hill
In this case, these forces would include the forces of friction down the hill and component of gravity down the hill.

The component of gravity, Fg

$$ F_{gs} = F_{g} \sin \theta $$

$$ F_{gs} = mgsin\theta $$

$$ F_{gs} = (7.0)(9.81)\sin35 $$

$$ F_{gs} = 39.3473 \text{ N} $$
The force of friction, $F_f$

$$F_f = \mu m g \cos \theta$$

$$F_f = (0.45)(7.0)(9.81)\cos\theta$$

$$F_f = 25.2872\, N$$

**Step III:** Calculate the net force in the direction of motion

In this case both the forces opposite to the direction of motion; and therefore both are negative

$$F_{net} = -F_{gx} - F_f$$

$$F_{net} = -39.3473 - 25.2872$$

$$F_{net} = -64.6345\, N$$

$$a = \frac{F_{net}}{m}$$

$$a = \frac{-64.6345}{7}$$

$$a = 9.2m/\, s^2$$ (opposite direction of motion)

In our case

m = 3 kg

$\theta = 6^\circ$

$\mu = 0.08$ ----for ball bearing to steel friction

Thus,

$$F_{gx} = 3 \times 9.81 \times \sin(6)$$

$$F_{gx} = 3.076\, N$$

Thus

$$F_f = \mu m g \cos \theta$$

$$= 0.08 \times 3 \times 9.81 \times \cos(6) = 2.34\, N$$

Thus

$$F_{net} = -F_{gx} - F_f$$

$$= 3.076 - 2.34 = 0.736\, N$$

Now, $F_{net} = (m)(a)$

$$a = \frac{F_{net}}{m}$$

$$a = \frac{0.736}{3}$$

$$a = 0.245\, m/\, sec^2$$

Now,

Co-relation between velocity and acceleration

$$V_f^2 = V_i^2 + a \times d$$

Here

$V_i = $ Final velocity of tray m/sec

d = distance travelled by tray = 1 m

As the initial velocity of tray $V_i = 0$

$$V_f = \sqrt{(a \times d)}$$

$$V_f = \sqrt{(0.245 \times 1)}$$

$$V_f = 0.495\, m/\, sec$$

Thus,

Time required to travel from point (a) to point (b) with mass of 3 kg and angle of inclination 6 degree, = Distance of point (a) to Point (b) / $V_f = 1/0.495 = 2.01\, seconds$.

Observations and graphs indicate that the theoretical time of transfer remains unchanged with increase in load but the actual time lowers with increase in load due to effect of gravitational acceleration. So also the theoretical time is less as compared to the actual time indicating friction present in slide and also due to the fact that the friction in rope and pulley is un-accounted in theoretical calculations.

### Economic Analysis of the Linear Conveyor:
Considering that the time required by the operator to move from Point (a) to Point (b) by time and motion study to be 10 seconds the effect of using gravity linear conveyor can be studied from figure below:

Thus from above analysis it is clear that the cost of Rs 660/- per shift per machine will be saved by the linear conveyor. Considering that the conveyor is operated for two shifts per day the cost of conveyor
will be recovered in \((16000 / (660 \times 2)) = 12\) months i.e. 1-year time.

8. CONCLUSION

After the fabrication and implementation of the effective material handling system, one could easily demonstrate the improved material handling. Both the system: Linear Material Handling (Powerless conveyors) and Revolving Material Handling Systems, shows how some simple and innovative ideas can be used to develop economical and non power consuming Material Handling Systems that can significantly relieve the operator fatigue, make the Material Handling safer along with the increased productivity. The project was just an effort to demonstrate the need and means of improving the Material Handling Systems and highlight the future scope of effective Material Handling.

9. FUTURE SCOPE:

Endless efforts can be made to continuously improve upon the material handling systems. The use of revolving material handling system concept would cut upon the cost and labour involved in material handling to a great extent.

It is possible to completely replace the powered conveyors by innovative thinking and utilizing gravity. The concept lets the door open for entire low cost automation of the line.

The project shows that the equipments can be easily implemented parallel to all similar application areas. The use of such material handling systems is possible in almost all small to large scale production industries. One may easily predict that the Revolving Material Transfer System would prove to be a revolutionary concept for industrial development.
