Impact Assessment of Fluorosis Mitigation Project, 
A Case Study of Nagour

Hukam Singh Raj Purohit¹, Dr. Bharat Nagar²

Jagannath University, Jaipur, Rajasthan

ABSTRACT

The present study has been undertaken to evaluate the impact assessment of the fluorosis mitigation project in the Nagour district (Raj). Nagour is a centrally located district of Rajasthan state of India which is a part of great Indian Thar Desert. Average rainfall in the district is 361.65 mm, which means quite low level in comparison with 531 mm in Rajasthan and 1200 mm in India. Also, the district has no perennial river and the main sources of water supply in the district is ground water which invariable does not confirm to BIS and WHO Standards as it contains excess of fluoride, nitrate and salinity. As per National Rural Water Quality Monitoring and Surveillance Programme, the Nagour is ranked second after Barmer that has 65.64 % quality affected drinking water sources. Despite this quality problem, most of area is over exploited. Moreover, cyclic drought has severely affected recharge of aquifers, which causes limited quantity of ground water.

Fluoride in drinking water of Rajasthan is found to originate from various rocks. These rocky belts extended from Delhi to Gujarat. The geological distribution of rocks in Rajasthan reveals that the fluoride yielding areas occupies large areas of eastern and southeast parts of the state. Also Rajasthan has mica mines, where the ground water is rich in fluorides.

Government of Rajasthan is implementing the fluorosis mitigation programme with the help of the three approaches i.e community based, school based and hospital based in the 986 villages and seven towns of the nagour district.

The impact assessment will help for the better understanding of community participation and the health effect of the interventions. The conclusions of the impact assessment may determine required recommendations and focus on community participation and improvement in their health. The conclusions drawn from this study will outline the need for capacity building of the doctors, paramedical staff and Panchayati Raj Institutions. Administrative capability and reduction in the diseases were evaluated using questionnaires and interpersonal communications.

Keywords: Fluorosis Mitigation, Community Based Approach, Hospital Based Approach, School Based Approach, Panchayati Raj Institutions, Interpersonal Communication.

1. INTRODUCTION

Nagour is a centrally located district of Rajasthan state of India which is a part of great Indian Thar Desert. Average rainfall in the district is 361.65 mm, which means quite low level in comparison with 531 mm in Rajasthan and 1200 mm in India. Also, the district has no perennial river and the main sources of water supply in the district is ground water which invariable does not confirm to BIS and WHO Standards as it contains excess of fluoride, nitrate and salinity. As per National Rural Water Quality Monitoring and Surveillance Programme, the Nagour is ranked second after Barmer that has 65.64 % quality affected drinking water sources. Despite this quality problem, most of area is over exploited. Moreover, cyclic drought has severely affected recharge of aquifers, which causes limited quantity of ground water.
recharge of aquifers, which causes limited quantity of ground water.

As per the norms of the government of Rajasthan service level of 100 LPCD 7 55 LPCD shall be maintained in the urban and rural area.

In the Nagour district service level in 11 towns of urban area in the district is ranging from 35 LPCD to 94 LPCD, Which are below the level of Government of Rajasthan.

Beside, 2 towns are getting water supply once in three days and 4 towns once in 2 days with average supply hour of 1 to 2 hours. Water supply is so limited because of the above situation.

2. Importance and relevance of the study

A. Fluorosis problem in Rajasthan

Fluoride in drinking water of Rajasthan is found to originate from various rocks. These rocky belts extended from Delhi to Gujarat. The geological distribution of rocks in Rajasthan reveals that the fluoride yielding areas occupies large areas of eastern and southeast parts of the state. Also Rajasthan has mica mines, where the ground water is rich in fluorides.

Over a period of time the number of villages affected by fluoride has increased i.e., in the year 1973, there were 1871 villages with fluoride levels over 3 mg/l. By 2001, this number has risen to 10,342 villages, an increase of more than five times. This makes Rajasthan the most severely affected state in India, with millions crippled as the result of consuming excessive amounts of fluoride. All the 33 districts have been declared as fluoride prone areas. Among all the district worst affected are Nagour, Jaipur, Sikar, Jodhpur, Barmer, Ajmer, Sirohi, Jhunjhunu, Churu, Bikaner, Ganganagar etc.

B. Who are the victims and spread of the disease?

The infants, children, pregnant lady, lactating mothers, adolescent girls and women of all age groups are the victims of fluoride poisoning. Besides, men of all age groups including boys in adolescence are victims of fluoride poisoning / fluoride toxicity and / or Fluorosis disease. In short the community in a
C. Overview of the problem of Fluorosis:
Observations are from endemic states for Fluorosis in India and Rajasthan in particular. Pregnant women suffer from loss of appetite, nausea, vomiting, etc., during early stages of pregnancy. They tend to consume during that period a variety of substances including churans. They also have special likes and dislikes. They tend to consume certain food items prepared either at home or collected from street vendors, viz. Panipuri, Golgappa, Dahibella, Namkins, Tamarind based chutneys sprinkled with special spices viz. Black Rock Salt (CaF$_2 = 157$ ppm Fluoride). It therefore emerges that pregnant women or lactating mothers can be exposed to Fluoride through food, beyond permissible limits (i.e. 1.0 mg/l or 1.0 ppm is the maximum body can tolerate) through any of the 5 major sources for fluoride viz

D. Fluoride from Food, food products and beverages:
Fluoride containing food, snacks and beverages has become very popular among the masses. The main source of Fluoride is by using black rock salt/ sandha namak or vrat ka namak. This has 157 ppm fluoride. Black rock salt containing spices are sold in the market. The people like it because of its aroma and tangy taste. Using Black rock salt containing spices are used in regular homes (rich or poor) to cook vegetables and Dhal. It is used to sprinkle over Dahi, Achar, Chutneys. It is also used to sprinkle over salads, fruit chat, lime juice. Every kitchen shall have a bottle of Black rock salt that is the experience. All street foods – viz. Bhel puri, Pani puri, Chaat, Golgappa, fruit juices and even cut fruits on road side smear black rock salt. Consuming Black tea or Lemon tea, contain considerable fluoride. Tea with calcium rich milk is safe. The Community may not know that Fluoride is a poison (Jahar) and at times, fluoride entry to the body is more than the untreated ground water. Awareness generation and Diet Editing would address the above issues.

E. Fluoride from drinking untreated ground water:
The concept that Fluorosis is caused by Drinking water Fluoride content, is true, but it is only one of the 5 main routes of Fluoride entry to the body. The FMP therefore is keeping the major focus on provision of safe water with Fluoride not exceeding the upper limit 1.0 mg/l (BIS guidelines less the better as Fluoride is injurious to health.

F. Fluoride from use of fluoridated dental products:
It is important to point out how the new-born, infants and children are affected by Fluoride poisoning as pregnant women ingest fluoride. The information is made clear so that appropriate strategy is developed and project implementation stages well defined. Packaged baby food, soya based baby foods have high fluoride.

G. Fluoride from Industrial Emission:
Inhaling fluoride dust and fumes, if residing near an industry using Fluoride salt or acid and emitting fluoride dust and fumes to the atmosphere / settles on agricultural crops is also causing damage to health. Those living near small and large scale industries, using Fluoride salt and / or Hydrofluoric acid, the dust and fumes can be inhaled is common. There are small and large scale Chemical industries in Nagaur. The community living in the neighbourhood would be watched for Fluoride poisoning.

H. Fluoride from drugs:
Fluoride containing drugs are often prescribed (available in different brand names)
For certain ailments for long term treatment to get relief from:

a) Otto sclerosis (Hard of hearing- Drugs contain Fluoride)
b) Depression (Majority of anti-depressants contain Fluoride)
c) Osteoporosis (Bone atrophy - Drugs contain Fluoride)

When the treatment is inevitable, the treating Physician may have to monitor the patient for GI problems, polypuria, polydipsia, fatigue and weakness due to Fluoride poisoning. Therefore the Doctors would be sensitized on all aspects of Fluorosis.
I. Water sources in Nagour
The surface water sources are none except a few salt lakes. There is a salt lake Sambhar Lake at Southwest of Didwana, having an area of 777 hectares. Nawa Tehsil also shares a part of Sambhur Lake in jaipur. There are 8 ponds in the district out of these, 5 are in Degana and 3 in Parbatsar blocks.

The deeper aquifers are being exploited extensively through low to median duty tube wells. The aquifer parameters of dug wells and tube wells have been studied from pumping tests. The yield of tube wells/dug wells in Nagour sandstone area varies from 6.5m³/hr to 36 m³/hr. the depth to water levels in Nagour district ranges from 10-80 meter below ground level. There is water level decline in many areas in the district, viz. Kuchaman city, Degana, Didwana and few others, and it is to the extent of 10 to 25 m has been recorded during the last 15 years.

II. Ground water quality
The water in Nagour district is generally brackish to saline with a few pockets having fresh water with electrical conductivity less than 2000 Micro Mohos/cm at 25 Degree Centigrade.

There are large areas with high fluoride

The fluoride content of Nagour district so far detected varies from 1 mg/l to 14.82 mg/l.

III. Health problem
In view of poor water quality and scarcity of potable water and high fluoride contents in ground water, the community suffers from all the three forms of fluorosis and associated health issues.

The study conducted in Nawa Tehsil of Nagour district, in January 2011, by R. Gautam and his team from Jaipur university of Rajasthan has shown fluoride in different zones ranged from 0.64 mg/l to 14.82mg/l; where 13% samples are found with fluoride in permissible limit. However 86.96 % has found beyond permissible limit.

Fluoride concentration ranged from (1) 1.10 to 14.82 mg/l in 3 different southeast zones (2) in the eastern zone, fluoride concentration was recorded and ranged from 1.52 to 5.13 mg/l (3) whereas, in south zone it was found between 0.64 to 3.63 mg/l.

IV. Sources of fluoride in ground water
It has been recorded in India week 2012 by Mohd. Arif from PHED Bhilwara, Rajasthan and his team, the sources of fluoride in ground water are from the following minerals found in the geological crust.

- Fluorite (fluorspar)
- Fluorapatite (apatite)
- Micas
- Biotite
- Muscovite
- Lepidolite
- Amphiboles
- Hornblende
- Tremolite
- Actinolite
- Topaz
- Rock phosphate
V. Fluorosis situation in Nagour district

![Graph showing awareness on fluorosis Tehsil-wise information]

![Graph showing children affected with dental fluorosis]

![Graph showing adult population affected with dental fluorosis (DF)]
VI. Flourisis disease
The people of Nagour district, those who are unwell and victim of fluorosis would seek assistance from doctors posted in government hospitals as well as in private hospitals.

As the patients, reaching out to hospitals is unfortunately not attended to, for a variety of reasons, it is necessary to address issues through a few selected hospitals/health delivery outlets in the districts. So that unwell and flourised victims from all parts of Nagour are able to reach health delivery outlets and receive proper care in hospitals and dealt with in a manner, they get relief from fluorosis disease which has not happened in Rajasthan state until date.

SUMMARY
- Children to the tune of 39.2 % (1,802 nos.) are reported with Dental Fluorosis
- Members of the households to the tune of 35.6 % (6,506 nos.) are reported with Dental Fluorosis
- Members of the households to the tune of 53.7 % (9,821 nos.) and 20 % (3,659 nos.) are reported with early warning signs and Skeletal Fluorosis respectively.
- The populations to the tune of nearly 69 % (12,633) are consuming food items contaminated with fluoride unknowingly.
- Nearly 44.2 % (1,584 nos.) families are aware about the Fluorosis disease.
3. METHODOLOGY
Objective: To mitigate Fluoride poisoning and Fluorosis disease in the population of Nagaur district, which include young and old, men and women of all age groups of urban and rural areas of the district, through approaches which are proven meaningful.

Methodology:
The fluorosis management component would be implemented through approaches given below:

A. Hospital base
- To construct five flouriosis diagnostic labs in government hospitals
- To procure and provide the necessary equipment, chemicals, plastics and glass wares and accessories
- To print adequate copies of pre-coded formats
- To develop capacity of laboratory technicians
- To develop capacity of ANMs & ASHAs
- To organize CME on correct diagnosis
- IEC activities
- To conduct first, second and third impact assessment

B. School base
- To update the list of the UPS, Secondary, senior secondary schools
- To coordinate with the school principals
- To develop the capacity of school teachers
- To screen dental fluorosis and bone deformity
- To identify and train health assistants
- To develop the capacity of health assistants
- To check hemoglobin level of the students
- To collect urine samples
- To organize group counseling
- To develop IEC material
- To conduct first, second and third impact assessment

C. Community base
- To identify and develop skills in field investigators
- To develop software using android technology and cloud networking to conduct HH survey
- To develop capacity of PRI members
- To conduct HH survey
- To collect and analyze all the drinking water sources
- To organize Focus group discussions
- To prepare social mapping through the PRA
- To organize street plays
- To conduct first, second and third impact assessment

Communication Approaches
Advocacy: To influence and engage decision makers to provide policies, funding organizational support and commitment for safe drinking water initiatives. The aim is to raise the issues of safe drinking water higher on policy agenda. This will increase commitment and action among decision makers and key influencers for adequate and safe drinking water. The advocacy through:
- Advocacy at state and district level
- Advocacy with other line department ministers
- Advocacy through media
- Advocacy with private sector and other organizations/
- Field visits
- Process documentations
- Seminars and conferences.

Community Mobilization
An approach used to initiate dialogue among community members to deal with critical issues of safe drinking water. This approach is especially effective in rural settings like in the District of Nagaur where communities from close-knit units; and if supported by opinion leaders and other influential sources can effect change from within, making it sustainable. Communities need to be involved and engaged in identifying their problems as well as solutions for them. Solutions given from outside the community are rarely sustained as there is no ownership. Thus it would be critical to engage with communities and ensure their participations. Frontline workers and PRI members can also play an instrumental part in promoting the mobilization in favor of certain behaviors.

Mass Media
Mass media is an important medium to communicate effectively with a larger number of people by leaving them with powerful image. It can overcome barriers of literacy and language and it is ideal for delivering a simple, clear and focused messages. Although there are several media dark areas in the state, there has been rapid progress towards increased TV and radio coverage and penetration. Mass media can support community mobilization and interpersonal communication efforts; promote specific behavior...
through multiple activities and products such as radio and TV Shows, newspapers and magazines; enhance the credibility of non-professionals such as community volunteers as reliable sources of information and services; convey important logistical information easily

**Outdoor and Folk Media**
According to the context, the stakeholders and the resources available a mix of different media will be used to sensitize on key aspect of the FMP and promote key behavior especially in media dark areas. The communication medium can be range from the more common ones such as hoardings and wall paintings as well as traditional ones, such as folk arts and theater and can be used as reinforcement to IPC and community mobilization activities. Combining different same messages related to key behavior also promotes effective behavior change. For example messages on print materials like flyers, leaflets and folk theater when combined with IPC can become more effective. These medium will be used to reinforce the key messages among the participants. Integrated approaches to ensure that all the messages related to safe drinking water are consistent and reinforced each other.

**Monitoring Indicators - IEC**
- % increase in the awareness level
- At present, level of awareness of fluorosis diseases is 44.2 %, which will be increased up to 100%
- In 1st phase, at least 44.2 % population which is already aware about the fluoride disease should not consume the fluoride water
- In 2nd phase rest of population i.e. 57.8 % population will be aware not to consume fluoride contaminated water
- 100% population should use the fluoride free food items
- % increase in the safe handling of drinking water.
- % increase in the rain water harvesting structures
- 100% population should use the fluoride free food items

**HRD Strategies and Activities**
- Creating awareness among stakeholders on water and fluorosis issues by educating them on impact of water and sanitation on health and poverty.
- Ensure behavior change in community on prevailing water management practices.
- Generating demand for potable water and sanitation facilities on the basis of felt need.
- Capacity building of all stakeholders to enable them to utilize and benefit from the water and fluorosis management.
- Convergence with related programme like MNREGA, NRHM, SSA, ICDS, 12th Finance Commission, BRGF etc.
- Problem mitigation, trouble shooting and debottlenecking
- Impact assessment

**Monitoring Indicators - HRD**
- Number of ASHAs, ANMs trained
- Number of doctors trained under CME
- Number of health workers trained
- Number of PRIs oriented
- Number of laboratory person trained
- Number of diet counselor trained
- Number of persons trained for Hb testing
- Number of field functionaries trained.
- Number of local persons trained

4. Steps for the interventions
**Sanitary survey**

5. CONCLUSIONS
The results of household Fluorosis health survey conducted in 50 villages of 8 Tehsils of Nagaur District revealed the following facts:

- Children to the tune of 39.2 % (1,804 nos. out of 4,603) are reported with Dental Fluorosis.
- Adult members of the households to the tune of 45.6 % (6,242 nos. out of 13,693) are reported with Dental Fluorosis.
- Members of the households to the tune of 53.7 % (9,821 nos. out of 18,296) and 20 % (3,659 nos. out of 18,296) are reported with early warning signs and Skeletal Fluorosis respectively.
- The population to the tune of nearly 69 % (12,633 out of 18,296) is consuming food items contaminated with fluoride unknowingly.
- Nearly 44.2 % (1,584 nos. out of 3582) families are aware about the Fluorosis disease.
- The average awareness on Fluorosis among the surveyed population in the 8 Tehsils of Nagaur District is less than 50 %. However, in Nagaur and Jayal Tehsils it is comparatively very low i.e. 8.3 % and 20 % respectively. In this regard, it is imperative to develop and disseminate appropriate communication materials depending on local conditions to increase the awareness level on Fluorosis. This would help in reducing the diseases burden due to Fluorosis.
- Nearly 10.3 % of households depend on private water tankers for their daily water needs. It would be appropriate to regulate and stipulate that water, which is a consumable entity like milk should be supplied in stainless steel tankers only. The water in stainless steel tankers can also be chlorinated in the tanker itself. Private contractors should not be allowed to provide water under unhygienic conditions and the quality of water need to be cross-checked.
- As nearly 69 % of surveyed respondents are consuming fluoride contaminated food items, Diet editing and Diet counselling need to be introduced with focus on elimination of excess fluoride ingestion through food, water and other sources.
- As pregnant and lactating mothers are also living in all the endemic Tehsils of Nagaur district, it is also important to popularize the message that Fluoride is a poison and that it leads to anaemia in pregnancy, low birth weight babies and also leads to abortions/intrauterine deaths. Appropriate communication strategy need to be developed and popularized through all avenues, so that adolescent girls, pregnant and lactating mothers are adequately sensitized.
- A high percentage of population i.e. 44.4 % to 62.3 % in all the 8 Tehsils suffer from early warning signs of Fluorosis, and as it is easily preventable, if all of them are aware about Do’s and Don’ts on Fluoride and Fluorosis problems.
- All the existing ground water sources need to be tested for fluoride and communities need to be sensitized on the harmful effects of consuming fluoride contaminated water, besides other food items. The survey data reveals that nearly
  - 35.6 % of households depend on tube well water. Open well and hand pump water are the 2nd highest sources i.e. 14.8 % and 13.9 % respectively. Consumption of safe water from existing safe sources should be focused upon.

**Result**

A. Household of the villages adopted the techniques for the DFU water
B. Household have realized the importance of defluoride water
C. Local population now understood the real cause of spread of fluorosis disease
D. Beneficiaries felt significant relief in several non-Skelton symptoms of flour sis i.e. recover of appetite, less backache, activity in daily routine life, decrease in gas formation, less thirsty, least joint pain, no stiffness in neck etc.
E. WATSAN committee, called pani samiti ( Village Water and Sanitation Committee-VWSC) have been constituted in all the GPs to self sustain the ongoing programme
F. There is active participation of community elected representative, local schoolteachers, revenue officials, ASHA, ANM, AWW, Para medical staff
G. Increased information education communication activities have awarded the people to use fluoride free water, uses of rain water and differential use of the water available.
H. Local persons trained
I. Close liaison between JICA, PHED, PRI, Health Department, and Education Department.
J. Proposed need base replication strategy stress for effective involvement of users and the government
K. Special schedules developed for house-to house survey, pre and post intervention medical examination of fluorosis patients and for fortnightly monitoring.
6. ACKNOWLEDGMENT
I wish to express my sincere thanks and deep sense of gratitude to the Head of Department and my guide and Dr. Bharat Nagar, without whom, the work would have not been possible. The confidence with which Dr. Bharat Nagar guided the work requires no elaboration. His timely suggestions given and encouragement shown, made me more confident in successfully carrying out my project work.
