²Lecturer, EI Department, Myanmar Aerospace Engineering University, Meiktila, Myanmar

ABSTRACT

The purpose of this paper is for the students to know the basic function of main components of refrigeration system. Theoretical and experimental of design calculation of main components and their results are reported in this paper. During the performance of testing, the length of expansion device is varied and the result data are also described. In this system, R134a refrigerant is used as working substance. Because it is now being used for a replacement of R-12 CFC refrigerant. It can be handled safely because it is not toxic, corrosive and flammable. Moreover, it has no damage effect to ozone layer and greenhouse.

KEYWORDS: main components, refrigeration system, expansion device, refrigerant, toxic, corrosive, flammable

INTRODUCTION

Refrigeration is the process of removing heat from a site where it is not necessary to transfer the heat to a place where it makes little or no difference. Refrigeration relates to the cooling of air or liquids and thus provides lower temperatures to preserve food processing, cool beverages, make ice, and for many other applications [1]. Nowadays, refrigeration system is widely used in residences, offices, buildings, air ports, hospitals and in mobile applications such as industrial freezers, electricity production, pharmaceutical, technical equipment, automobiles, aircrafts etc.

FUNCTION OF MAIN COMPONENTS

A refrigeration system has mainly five essential components:

1. Evaporator
2. Compressor
3. Condenser
4. Expansion valve
5. Refrigerant

Compressor

The main function of the compressor is to suck the low pressure vapour from the evaporator and force it into the condenser. The refrigerant is continuously circulated by the compressor through the refrigeration system. to reduce the volume and increase the pressure of refrigerant. The capacity of refrigeration system depends on the capacity of compressor. This system is used hermetic type compressor to reduce noisy and leakage. And it is a portable type and can be replaced with another.

Evaporator

The function of the evaporator is to receive liquid refrigerant from the expansion device and to bring it in close thermal contact with the load. The refrigerant takes up its latent heat from the load and leaves the evaporator as a dry gas. Evaporators are classified according to their refrigerant flow pattern and their function [1]. It is used in the low pressure side of the refrigeration system.

2.3. Condenser
The purpose of the condenser is to remove the hot, high-pressure gas or vapor refrigerant from the compressor and cool it to remove first the superheat and then the latent heat, so that the refrigerant will condense back to a liquid. In nearly all cases, the cooling medium will be air or water or combination of the two[1]. As condenser is one of an important device for the refrigeration system, it is used in the high pressure side of the refrigeration system.

2.4. Expansion Device
It is also known as a metering device. The main performance of the expansion device is to control the flow of sufficient pressure differential between the high and low pressure sides of the system. It is used for metering the correct amount of refrigerant to the load on the evaporator [2].

2.5 Refrigerant
The refrigerant is usually a liquid or gaseous compound. It easily absorbs heat from the fluid medium and can provide cooling or air conditioning in combination with other components such as compressors and evaporators. Without refrigerant, there would be no air conditioning and refrigeration technology.

3. LAYOUT OF LAB BASED REFRIGERATION SYSTEM

The design and construction of all components for lab based refrigeration system is as shown in Figure 5. It is a kind of domestic refrigerator. All components are fixed firmly on the stand board. The testing results are based on different lengths of capillary tube. The lengths of capillary tube were 0.9144 m, 1.524 m and 2.135 m. Because this lab based refrigeration system was only the project.

We observed that during the testing, suction pressure, discharge pressure and others are changed. Running time is 15 minutes. The components of this system are;
A. Compressor
B. Condenser
C. Evaporator
D. Expansion device
E. High pressure gauge
F. Low pressure gauge
G. Filter drier
H. Sight glass
L. Shutoff valves

4. DESIGN SPECIFICATIONS OF MAIN COMPONENTS

4.1. Detail Designs of Compressor
For the volumetric efficiency of compressor,

$$\eta_v = 1 + c - c \left( \frac{P_2}{P_1} \right)^{\frac{\gamma}{2}}$$

(1)

Where,
\(\eta_v\) = volumetric efficiency
\(P_1\) = suction pressure, Pa
\(P_2\) = delivery pressure, Pa
\(c\) = clearance (between 2% and 5%)
\(\gamma\) = Isentropic index

For piston diameter and stroke length,

$$P_D = \frac{\pi D^2}{4} \times L \times N \times n$$

(2)

Where,
\(N\) = compressor speed, rpm
\(n\) = no. of piston
\(P_D\) = Piston displacement, cm³/rev
\(L = 0.8D\) (Hermetic type compressor)
For required work done of compressor,
\[ W_c = \frac{\gamma}{\gamma - 1} \frac{P_2}{P_1} V \left( \frac{P_2}{P_1} \right)^{\frac{\gamma - 1}{\gamma}} - 1 \] (3)

Where,
\( W_c \) = work done of compressor, kJ/cycle

For the required actual power of compressor,
\[ P = \frac{W_c \times N}{60} \] (4)

Where,
\( P \) = actual input power, kW

For input power of compressor,
\[ \text{Input power} = \frac{W_c}{\eta_{\text{mech}}} \] (5)

Where,
\( \eta_{\text{mech}} \) = mechanical efficiency
\( W_{\text{input}} \) = input power of compressor, W

4.2. Heat Transfer in Condenser

For heat transfer in condenser,
\[ Q_{\text{con}} = U_{\text{copper}} \times A_{\text{con}} \times \Delta T_m \] (6)

Where,
\( Q_{\text{con}} \) = heat rejected in condenser, W
\( U_{\text{copper}} \) = overall heat transfer coefficient of air velocity, (60-65 W/m²K)
\( A_{\text{con}} \) = area of condenser, m²

For mean temperature of the condenser,
\[ \Delta T_m = \frac{(T_i - T_{a,in}) - (T_i - T_{a,out})}{\ln \left( \frac{(T_i - T_{a,in})}{(T_i - T_{a,out})} \right)} \] (7)

Where,
\( T_i \) = condensing temperature, °C
\( T_{a,in} \) = air inlet temperature, °C
\( T_{a,out} \) = air outlet temperature, °C

For heat transfer area of the condenser,
\[ A_{\text{con}} = \pi d_i \times L_{\text{con}} \] (8)

Where,
\( d_i \) = outside diameter of condenser, m
\( L_{\text{con}} \) = length of the condenser, m

4.3. Detail Designs of Evaporator

\( T_s \) = ambient temperature = 306 K
\( T_e \) = evaporator outlet temperature = 263 K
\( T_e \) = evaporator temperature = 245 K

For Log mean temperature difference,
\[ \Delta T_m = \frac{T_{d1} - T_{d2}}{\ln \left( \frac{T_{d1}}{T_{d2}} \right)} \] (9)

Where,
\( T_{d1} \) = maximum temperature difference, °C
\( T_{d2} \) = minimum temperature difference, °C
\( \Delta T_m \) = log mean temperature difference, °C

For the capacity of evaporator,
\[ Q_{\text{eva}} = U_{\text{eva}} \times A_{\text{eva}} \times \Delta T_m \] (10)

Where,
\( Q_{\text{eva}} \) = capacity of evaporator, W
\( U_{\text{eva}} \) = overall heat transfer coefficient, W/m²K
\( A_{\text{eva}} \) = area of the evaporator, m²

For the length of evaporator tube,
\[ A_{\text{eva}} = \pi D_{\text{eva}} \times L_{\text{eva}} \] (11)

Where,
\( L_{\text{eva}} \) = length of the evaporator tube, m
\( D_{\text{eva}} \) = outside diameter of evaporator, m

For overall heat transfer coefficient of evaporator,
\[ U_{\text{eva}} = \frac{1}{h_r + \frac{x_a}{k_a} + \frac{1}{h_1}} \] (12)

Where,
\( h_r \) = heat transfer coefficient of refrigerant, W/m²
\( h_1 \) = heat transfer coefficient of air side, W/m²K
\( x_a \) = thickness of evaporator, °C
\( k_a \) = thermal conductivity of aluminum, W/mK

Air side heat transfer coefficient can be calculated the following equation,
\[ h_1 = 1.24 \left[ \frac{\Delta T_i}{D} \right]^{\frac{1}{3}} \] (13)

Where,
\( \Delta T_i \) = sub cooling temperature difference, °C

For modified latent heat transfer coefficient,
\[ h_{lg1} = h_{lg} + \frac{3}{8} c_i \Delta T \] (14)

Where,
\( h_{lg} \) = latent heat, kJ/kg
\( h_{lg1} \) = modified latent heat, kJ/kg
\( c_i \) = correction factor
For heat transfer coefficient of refrigerant,

\[
h_{r} = 0.555 \left[ \frac{g \times \rho_i \times (\rho_i - \rho_g) \times k_r \times \rho_g}{\mu \times \Delta T_i \times D_i} \right]^{\frac{1}{4}}
\] (15)

Where,
- \( k_r \): thermal conductivity of refrigerant, W/mK
- \( \rho_i \): density of refrigerant, kg/m³
- \( \rho_g \): density of gas, kg/m³
- \( g \): gravitational force, m/s
- \( \mu \): viscosity of refrigerant, kg/ms

4.4. Expansion Device

Inside diameter = 0.5 mm to 2.25 mm
Length = 0.5 mm to 5 m

5. RESULTS AND DISCUSSIONS

5.1. Design Calculation for Compressor

\( P_1 = 96.5 \) kPa
\( P_2 = 2413 \) kPa
\( c = 2\% \)
\( \gamma = 1.14 \)

By using Equation (1),
Volumetric efficiency of compressor is 
\( \eta_v = 68\% \)

By using Equation (2),
No. of piston, \( n = 1 \)
Compressor speed, \( N = 3000 \) rpm (2 poles compressor motor)
\( L = 0.8D \) (Hermetic compressors)
Piston displacement is
\( P_0 = 9.2 \) cm³/rev
Piston diameter, \( D = 24 \) mm
Piston stroke length, \( L = 19 \) mm

By using Equation (3),
\( V_i = 9.2 \) cm³/rev
\( \gamma = 1.14 \) (isentropic compression)
Required work done of compressor is 
\( W_c = 3.5047 \times 10^{-3} \) kJ/cycle

By using Equation (4),
Actual power to drive the compressor,
\( P = 0.1752 \) kW

By using Equation (5),
\( \eta_{mech} = 0.92 \)
Input power of compressor,
\( W_{input} = 3.809 \times 10^{-3} \) kW

5.2. Design Calculation of Condenser

\( d_i = 0.004 \) m
\( T_i = 65\text{°C} \)
\( T_{s,in} = 32\text{°C} \)

5.3. Design Calculation of Evaporator

By using Equation (6),
\( Q_{con} = 323 \) W
Area of condenser is
\( A_{con} = 0.195 \) m²

By using Equation (7),
Mean temperature difference is
\( \Delta T_m = 27.6 \text{°C} \)

5.4. Selection of Expansion Device

Capillary tube is one of the important types of used in expansion device. The selection of capillary depends on the compressor work done. Due to the testing results, capillary tube length is inversely proportional to the refrigerant flows. And then, condenser
pressure and evaporator pressure are increased. According to the experiment, the suitable length of the capillary tube is between 1.524 m and 4.877 m.

6. CONCLUSION
This lab based refrigeration system analyzed the detail designs of compressor, condenser, evaporator and coefficient of performance by varying the capillary tube length.

This system is simple in structure and easy to maintain. It can be used for laboratory experiments of basic refrigeration processes and principles of each component. It is fairly inexpensive and therefore much suitable for mechanical engineering students. It can also be used as teaching aids.

The design calculations and results will help for other new designs.
