## ABSTRACT

The aerodynamics plays an important role in the design process of the automotive. So CFD (computational fluid dynamics) is the fluid mechanics branch that uses algorithms and numerical analysis to analyze problems of fluid flow that is to investigate the fluid flow. It is basically originated from the Naviers-Stokes equation. In this we work on solid works software to analyse the CFD on the design of roll cage of a vehicle named effi cycle. This reviews the analysis on the various members of roll cage. Here the analysis of wheel hub, paddle hub, and the roll cage on the solid works software.

## INTRODUCTION

Research is going on the automotive field. Fuel economy is one of the major concerns faced by CI engines. As of increasing growth of industries, the aerodynamically analysis of vehicle helps in reducing the drag force. Various properties are involved in a typical fluid dynamics problems like velocity, pressure, temperature with respect to space and time. CFD helps in increasing the growth by reducing the complex problems in engineering.

## Part 1: Analysis of Wheel hub

### Assumptions:

- Wheel hub analysis was carried out assuming that the vehicle is having a mass of 240kg.(including the mass of both the drivers and dead weight). The front wheels' experience bump on one side and droop on another. So, the normal reaction shifted to one wheel which is further transferred to the hub.
- Outer part of the hub is fixed and a force is applied at the lower surface of the hub.
- During the hub designing, force acting is considered to be maximum while torsion condition.
- The outer periphery of the hub is fixed with zero degree of freedom constraints.
- The mesh generated during this process is beam mesh with defined mesh control and fine density.

### Calculations:

This is the case of torsion analysis the forces applied are same of torsion analysis on the hub.

For Torsion, the twisting effect is assumed to be one fourth of the force in front impact.

$$\begin{aligned}\text{Force} &= (\text{front impact force})/4 \\ &= 10700/4 \\ &= 2675 \text{ N}\end{aligned}$$

Hence, load applied on the hub is =2675 N.

### Analysis Results:

#### 1. Maximum Deformation: 0.01908 mm

## 2. Maximum Stress Generated: 72.8 M Pa

Model name: front hub mounting simulation  
Study name: Static (3-Default)  
Plot type: Static displacement (Displacement)  
Deformation scale: 0.000001

## 3. Factor of Safety: 3

Model name: front hub mounting simulation  
Study name: Static (3-Default)  
Plot type: Factor of Safety (Factor of Safety)  
Criterion: Automatic  
Factor of safety distribution: Min FOS = 3

### Optimization:

- Hub thickness was increased due to less factor of safety in initial stage of designing.
- Appropriate material was considered for safe design.
- The point of fixture was modified for safe design.

## PART 2: ANALYSIS OF PADDLE HUB

### Assumptions:

- Outer part of the hub is fixed and a torque is applied at the inner part of the bearing in the hub.
- During the hub designing, torque acting is considered to be maximum while starting paddling.
- It is assumed that each driver exerts a force of 200 N on paddles while paddling.
- The outer periphery of the hub is fixed with zero degree of freedom constraints.
- The mesh generated during this process is beam mesh with defined mesh control and fine density.

### Calculations:

Let us assume that at the time of starting paddling, each driver exerts a force of  $F=300\text{N}$  (value of paddling force once the vehicle comes into motion is assumed to be 150 N)

Distance of paddle center and paddle extreme is equal to 0.2m, i.e.  $x = 0.2\text{m}$

Hence, torque acting on paddle hub

$$T = F \cdot x$$

$$T = 300 \cdot 0.2$$

$$T = 60\text{ Nm}$$

Hence, a torque of 60 Nm acts on each paddle hub.

### Analysis Results:

## 1. Maximum Deformation: 0.00733 mm

Model name: paddle hub  
Study name: Static (3-Default)  
Plot type: Static displacement (Displacement)  
Deformation scale: 0.000001

## 2. Maximum Stress Generated: 30.65 M Pa.

Model name: paddle hub  
Study name: Static (3-Default)  
Plot type: Static modal stress (Stress)  
Deformation scale: 0.000001

## 3. Factor of Safety: 7

Model name: paddle hub  
Study name: Static (3-Default)  
Plot type: Factor of Safety (Factor of Safety)  
Criterion: Automatic  
Factor of safety distribution: Min FOS = 7

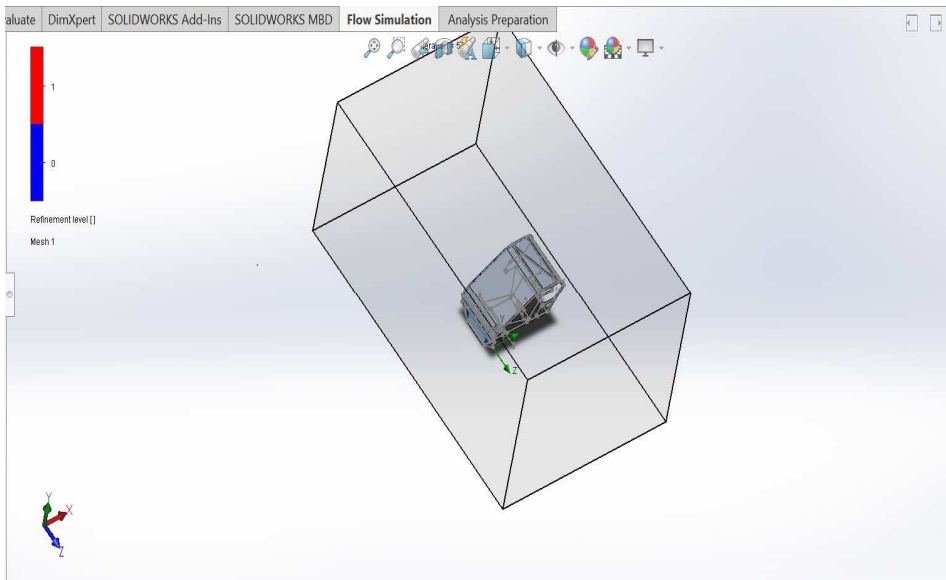

### Optimization:

- Hub thickness was increased due to less factor of safety in initial stage of designing.
- Appropriate aluminum material was considered for safe design.

## PART 3: ANALYSIS ON ROLL CAGE.

### STEPS:

- Select the roll cage.  
Make it in flow simulation.
- Select the contours.  
(pressure, flow, mesh)
- Select in the air field.

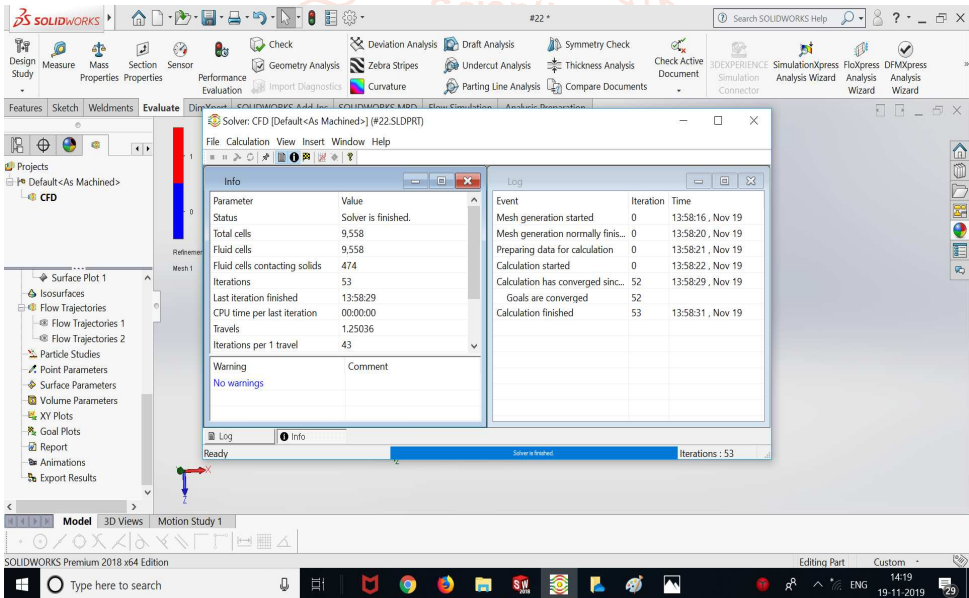

**MATERIAL: (AL 6063 T6 38\*1 34\*1\*2)**

**ASSUMPTIONS:**

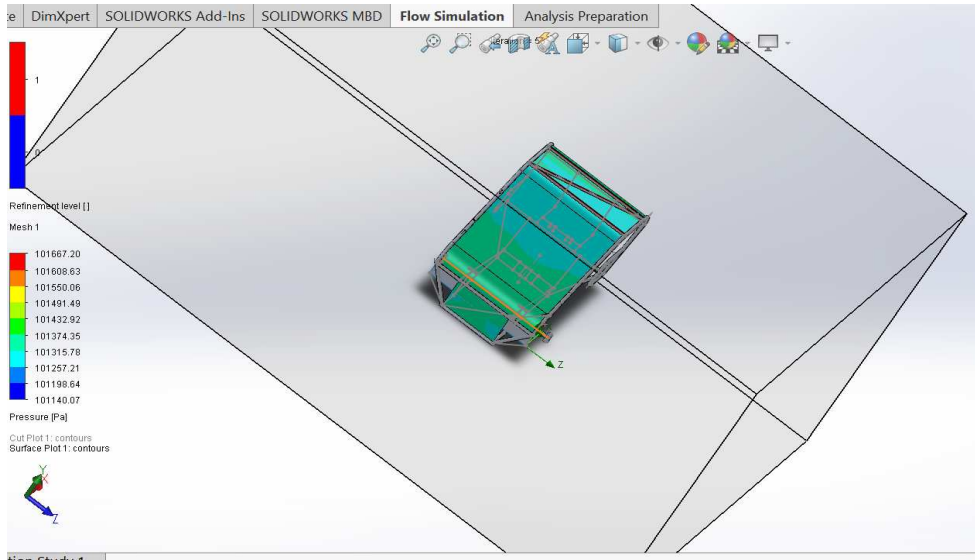

- The material of frame is considered to be isotropic and homogenous.
- The tube joints are considered to be perfect.

**CALCULATION:**

**ANALYSIS:**

**1. PRESSURE CONTOUR**

## 2. FLOW TRAJECTORY:

## 3. MESHING:

## CONCLUSION:

1. While the analysis of wheel hub we can conclude that the maximum deformation is 0.01908mm and the maximum generated stress is 72.8MPa with a FOS 3.
2. While the analysis of paddle hub we can conclude that the maximum deformation is 0.0073mm and the maximum generated stress is 30.65 M Pa with a FOS 7.
3. On analysis of roll cage we analysis for pressure contour, flow trajectory, meshing.
