ABSTRACT

Lung diseases have been a worldwide health problem, with high endemicity in developing countries. Bronchopneumonia remains the main disease of the lung. Despite advances in modern medicines, there is no-effective drug available that stimulate lung function, offer protection to the lung from damage or help to regenerate pulmonary cells destroyed by disseminated bacteria. There is an urgent need for effective drugs to replace/supplement those in current use. This study was embarked upon to evaluate the effect of *Asplenium bulbiferum* leaf extracts on nosily infected mice with *streptococcus pneumoniae* isolate of suspension containing 5×10^6 cells/ μ l. *Streptococcus pneumoniae* was obtained from human specimen, identified through cultural, morphological and biochemical examination, in addition, polymerase chain reaction (PCR) technique was performed using universal primers to support the identification process. The antibacterial activity was carried out using agar well diffusion technique. Tube dilution technique was used to determine the minimum Inhibition Concentration (MIC) and Minimum Bactericidal Concentration (MBC) using double fold serial dilution at concentrations of 400mg/ml to 25mg/ml. The effect of the leaf extract was evaluated by treating *mus musculus* mice (WBC count 4.5×10^3) with sub-MIC of *A. bulbiferum* extracts after nosily infected with *S. pneumoniae* and appearance of disease septum with 11.3×10^3 WBC count after 5days from infection. The photochemical analysis revealed the presence of alkaloids; phenolics, tannins, saponins, flavonoids, steroids and glycosides. The ethanolic extract exhibited more activity than the aqueous extract against *S. aureus* most followed by *S. pneumoniae*, *H. influenza* and *K. pneumoniae* was the least. After treating the infected mice with the plant extract and after 6 days from infection, the WBC count reduced to $5.1 \times 10^3 \mu$ l which is normal range and the mice were healthy with good physiological behaviour.

The infected mice and untreated with extracts, the WBC and other immunological parameters remain high even after 16 days from infection. The study showed that *Asplenium bulbiferum* possessed antibacterial properties and should serve as alternative therapy for ameliorating lung infections.

KEYWORDS: Lung, In-vivo, wbc, Mus-mus, fern

INTRODUCTION

Lung diseases remain one of the major threats to public health and are worldwide problem (Asha and Pushparadan, 2018). They are mainly caused by bacterial and viruses, chemicals, fumes, organic and inorganic substances, radiation cancer treatment, administration of chemotherapy drugs, autoimmune

disorder and infections (Robert *et al.*, 2019; Tortora *et al.*, 2015 and Khare *et al.*, 2016). Infection due to bacteria is the main cause of a number of respiratory illness. Lung inflammations or infections include common cold and cough, chronic obstructive pulmonary disease; cystic fibrosis (C.F.); asthma;

pneumonia, pleurisy, etc (Gina, 2019, Khare *et al.*, 2019; Robert *et al.*, 2019).

In spite of the tremendous advance in modern medicine, there is no effective drug available that stimulates lung function, offer protection to the lungs from damage or help to regenerate thoracic cells due to multiple drug resistance by microbes (superbug) such as methicillin resistance *staphylococcus aureus* (MRSA) (Chattopadhyay, 2013).

Asplenium bulbiferum (fern) commonly known as “Ibu” in south eastern Nigeria belongs to the family pteridophytes, and a native in India, North America, Europe, Iran, Northern Australia, Malaysia, Papua New Guinea, and other parts of Asia. *Asplenium bulbiferum* grows on a variety of trees particularly palm trees, mango, and lime across Nigeria (Scheutpels *et al.*, 2017). *Asplenium bulbiferum* is an evergreen parasitic plant growing on the branches of trees where it forms bushes 3 to 7 feet in diameter.

Asplenium bulbiferum contains glycoside, saponin, alkaloids, flavonoids, tannins, phenols, and steroids Trease and Evans (2016), Sofowora (2019). *Asplenium bulbiferum* (fern) is said to be derived from the celtic word” all heal”. This correlates with its historical use for every ailment (Khare, 2016). Some studies have investigated *Asplenium bulbiferum* scientifically and it was found to possess a number of notable pharmacological effects including lung diseases (Gupta, 2014), men and women’s sterility, nasal polyps, kidney infections, gonorrhoea, rheumatism, headache, asthma, wound healing and so many others (Vasudev, 2019), Wang *et al.*, 2015; Khare and Adekunle, 2019). Rudoff steiner (1861-1925) created what is known as anthroposophical medicine. This mystical system used a variety of unusual remedies including special extracts of *Asplenium bulbiferum* for infection.

Despite these medicinal roles played by *Asplenium bulbiferum* in human body, no work has been published on its ability to alleviate lung infection induced by bacteria such as *streptococcus pneumoniae* as well as secondary infections caused by chemicals thus; this work was undertaking to evaluate the antibacterial activities of *Asplenium bulbiferum* leaf extracts to alleviate lung infection induced by bacteria such as *streptococcus pneumoniae*.

Materials and Methods

Sample collection and classification

In this study, sputum samples were collected from patients suffering from lung diseases at General Hospital Onitsha, St. Charles Borromeo Hospital and Nnamdi Azikwe University Teaching Hospital,

Nnewi. Each was classified according to names, genders and age of the patients.

Collection of sputum sample was as follows:

Two hundred (200) samples were collected from each of the above mentioned hospitals for analyses.

Each patient was given two containers labelled specimen A and B respectively, the container was dried, clean, wide-necked, and leak-proof. Then the patient was requested to cough deeply to produce sputum specimen into the container (Monica Cheesbrough *et al.*, 2015).

Collection of leaf samples

Collection, authentication and processing of plant materials

The fresh leaf of *Asplenium bulbiferum* was collected from Umuoma Uli, Ihiala Local Government Area, Anambra State, Nigeria. The plant materials were identified and authenticated by a Botanist at the Biological Science Department, Nnamdi Azikwe University, Awka, Nigeria. Confirmation of taxonomic identity of the plants was achieved by comparison with voucher specimens kept at the Herbarium of the Department of Biological Sciences, UNIZIK and use of documented literature from Dalziel (2016). The plant materials were air-dried in the laboratory for four weeks and then ground into powdered form, weighed and kept ready for extraction of active ingredients using electric grinder and stored for future use (Nwobu *et al.*, 2016).

Preparations of Media for Isolation

The media used for this study included: Nutrient agar (oxid), blood agar, chocolate agar (oxid), Mueller Hinton agar (oxid) and Nutrient broth (oxid). The media were prepared according to the manufacturer’s instruction and sterilized by autoclaving at 121°C, 15psi for 15 minutes.

Isolation and Identification of Test Organism

The test organisms used in this work were isolated from the sputum of the infected patients. The purulent part of the sputum was washed in about 5ml of sterile physiological saline. The samples were plated on blood agar and chocolate agar plates and incubated anaerobically by using gas pak at 37°C for 24 h. The organisms obtained were aseptically sub-cultured on nutrient agar plate and incubated at 37°C for 24 h. The pure culture of the test organism was identified using morphological characteristics, gram staining and biochemical reactions (Reynold, 2015).

Extraction

The powdered plant material (20g) leaf was percolated in ethanol (200ml) in 11 capacity conical flasks, stoppered and kept for two weeks with intermittent shaking. The percolates were filtered

with Whatman's No. 1 filter paper. The extracts were concentrated at 40°C under reduced pressure using rotary evaporator (RI-10). The same quantity of plant material was again percolated with distilled water for one week and after filtration, the aqueous extract was concentrated in hot oven at 40°C (Nwobu *et al.*, 2016). The concentrated extracts were labelled ALE (*Asplenium bulbiferum* ethanol leaf extract) and ALE (*Asplenium bulbiferum* aqueous leaf extract).

Phytochemical Analysis

Phytochemical analysis for qualitative detection of alkaloids, flavonoids, tannins and saponins was performed on the extracts as described by Trease and Evans (2019), Sofowora (2018).

Quantitative determination of the presence of phytochemicals

Alkaloids

Five milliliters (5 ml) of the sample was mixed with 96% ethanol-20% tetraoxosulphate (vi) acid (1:1). One milliliter (1 ml) of the filtrate from the mixture was added to 5 ml of 60% H₂SO₄ and allowed to stand for 5 minutes. Reading was taken at absorbance of 565 nm.

Glycosides

This was carried out using Buljet's reagent. One gram (1 g) of the fine powder of the sample was soaked in 10 ml of 70% alcohol for 2 h and then filtered. The extract was then purified using lead acetate and disodium hydrogen tetraoxosulphate (vi), (Na₂HPO₄) solution before the addition of freshly prepared Buljet's reagent. The absorbance was taken at 550 nm. Flavonoids

Five millilitres of the extract was mixed with 5 ml of dilute hydrochloric acid (HCl) and boiled for 30 minutes. The boiled extract was allowed to cool and then filtered. One millilitre (1 ml) of the filtrate was added to 5 ml of ethyl acetate and 5 ml of 1% ammonia solution. The absorbance was taken at 420 nm.

Phenolics

Ten millilitres (10 ml) of the sample was boiled with 50ml acetone for 15 minutes. Five millilitres of the solution was pipette into a 50 ml flask. Then, 10 ml of distilled water was added. This was followed by the addition of 2 M NH₄OH and 5ml of concentrated amyl alcohol. The mixture was left for 30 minutes and absorbance was taken at 505 nm.

Tannins

Ten millilitres (10 ml) of the sample was pipette into 50 ml plastic bottle containing 50 ml of distilled water. This was shaken for 1 h on a mechanical shaker. The solution was filtered and 5 ml of the

filtrate was mixed with 2 ml of FeCl₃ in 0.1 NHCL. The absorbance was read at 120 nm.

Steroids

The extract was eluted with normal NH₄OH solution. Two millilitres (2 ml) of the eluate was mixed 2 ml of chloroform in a test tube. Three (3 ml) of ice cold acetic anhydride was added to the mixture and two drops of concentrated H₂SO₄ was continuously added to the mixture and allowed to cool. The absorbance was taken at 420 nm.

Saponins

Five millilitres (5 ml) of the sample was dissolved in aqueous methanol. Then, 0.25 ml of aliquot was taken for spectrophotometric determination for total saponins at 544 nm.

Determination of Extractive Value

The concentrations of the extracts were determined by evaporating 1.0 ml of the extracts in evaporating dish of known weight in an oven to dryness and weighed. The dish containing the residue was allowed to cool and then weighed. The weight of the residue was obtained by subtracting the weight of the empty dish from the weight of the dish and residue. The above process was repeated in duplicate (Nwobu *et al.*, 2016).

Maintenance of Test Organisms

The isolated test organisms were used for the antibacterial sensitivity testing. Prior to the test, the organisms were sub-cultured on nutrient agar plate at 37°C for 24 h. Then the 24 h cultures were transferred into nutrient broth and incubated anaerobically using gas pak at 37°C for 24 h (Cheesbrough *et al.*, 2015).

Standardization of Inoculum

The inocula were prepared from the stock cultures, which were maintained on nutrient agar slant at 4°C and sub-cultured onto nutrient broth using a sterilized wire loop. The density of suspension inoculated onto the media for susceptibility test was determined by comparison with 0.5 McFarland standard of Barium sulphate solution (Cheesbrough *et al.*, 2015).

Test Organisms

Staphylococcus aureus, *Streptococcus pneumoniae*, *Streptococcus klebsiella* and *Haemophilus pneumoniae* were bacterial isolates from sputum samples. This was followed by washing with physiological saline and streaking sputum samples on appropriate media for isolation. Cultural and morphological identification as well as biochemical characterization of isolates using protocol described by Cheesbrough *et al.*, (2015) was carried out. Pure cultures of the isolates were maintained in appropriate media for future use.

Preparation of Test Sample

In this study, concentrations of 400 mg/ml of the extracts were used to screen for the antimicrobial activity. This was done by using the modified method of NCCLS (2013). Here, 2.5 g of the extract was dissolved in each of the extracting solvents.

Antibacterial Assay

Medicinal plants using agar well diffusion method.

This was carried out by using agar well diffusion techniques. In this method, each of the labelled plates was uniformly inoculated with the organisms using pour plate techniques. A sterile cork borer of 6 mm diameter was used to make wells on the medium. 0.1ml of the various extract concentrations were dropped into each labelled well. After that, the plates were incubated anaerobically at 37°C for 24 h. Antibacterial activity was determined by measuring the diameter of zones of inhibition (mm) produced after 48 h of incubation. 0.05% Cephalosporin was used as control.

Determination of minimum inhibitory concentration (MIC)

Here, various concentrations of the extracts were obtained using double- fold serial dilution. Each dilution was assayed against the test bacterial using tube dilution techniques. One millilitre of test organism was added into each dilution incubated anaerobically at 37 for 24 h. The MIC was defined as the lowest concentration able to inhibit any visible bacterial growth. This was determined and recorded (Shahidi-Bunjar, 2014).

Determination of minimum bacterial concentration (MBC)

Here, equal volumes of various concentrations of those tubes that did not produce any growth from MIC was plated on fresh sterile pure plate and incubated anaerobically at 37°C for 24 h. The lowest concentration of the extracts that killed the test bacterial was taken as the MBC (Shahidi-bunjar, 2014).

Acute Toxicity Studies

This was carried out using the modified method of UKWE and EZE (2014). The animals (MICE) were grouped into ten (10) and each group comprises of three mice.

The average weight of each group was taken using electric weighing balance. Group 1 and 2 were administered orally with 1.0ml of the extracts (400mg/ml) these mice were left for 72 h and result were recorded.

Pathogenicity

In this study, pathogenicity of the isolate S6B was carried out using the method of Kumar *et al.*, (2019).

The test animals used for this study was mice (breed in animal House, Edem- Ani Road, Nsukka, Enugu State. Both male and female laboratory *mus musculus* (white albino) weighing 30-35g, 10-12 weeks in age. They were kept singly in metabolic cages under room temperature 35-37°C. The mice were randomly divided into 2 groups, each containing 7 and 3 mice respectively. A total number of 10 mice were used for this study. The above two (2) groups were called immunocompromised and immunocompetent. The immunocompromised include (A,B, C, E, F and G) while the immunocompetent include (H,I and J). The immunocompromised were starved for two days while the immunocompetent were fed very well with 20g of mice chow and water. The mice were infected with *streptococcus pneumoniae* S6B isolate of suspension containing 5×10^6 cells ml (Song *et al.*, 2017) by exposing them to the aerosol coming out from the prepared isolate put in a special container intranasally (i.n.). The mice were observed for clinical manifestation for 4-16 days to detect changes such as noticeable labored breathing, dyspnoea, heavy mucus on their nostrils, unusual snizzing, etc. When the symptoms of disease appeared, animals were isolated and placed in a separate cage with the recommended food and water. Among the immunocompromised group, mice A, C, D and E. Note, mouse B showed no symptoms of disease after exposure to the isolate. Mice A, C, D and E were administered the sub-MIC of plant extract twice daily orally for 6 consecutive days using different concentrations of the extracts (400,200,100 and 50mg/ml). Then mouse F was administered the cephalosporin (positive control) and the last (mouse G) was left untreated. The remaining three mice were exposed to distilled water, cephalosporin and vancomycin respectively. The distilled water served as negative control while cephalosporin and vancomycin were used as positive controls.

Toxicology Testing

Total WBC count: Blood samples were obtained from the lung anesthetized mice as described above and put in heparinised tubes, mixed well, then the WBC was counted using culture instrument and classical way (Thmel *et al.*, 2014).

In vivo effect of *asplenium bulbiferum* leaf extract on the above animals used for pathogenicity testing were adapted and used for this study.

In vivo antimicrobial activity: nosely infected mice with *streptococcus pneumoniae* S6B isolate of suspension containing 5×10^6 cells ML (Song *et al.*, 2017). The mice were randomly divide into 3 groups the first group include mouse H (disease control) received distilled water only, the second group

include (A, C, D, and E) showed clinical manifestation after exposing them to the challenges of bacterial suspension and also received the sub-MIC of plant extract; then the third group which includes (mouse G was left untreated while mouse F received cephalosporin antibiotics.

Enumeration of isolate cells in the blood was performed according to Goden *et al.* (2015) and Kuo

et al. (2015) during 0,4,8 and 12 days from infection. The frequencies of WBC and deferential WBC were evaluated (Thmol *et al.*, 2014) for 4 consecutive days and the animals were observed for 12days from the day on which the disease was induced and the death rate was recorded.

RESULT

The phytochemical studies of the constituents of *Asplenium bulbiferum* leaf extracts revealed the presence of alkaloids, saponin, flavonoids, phenolics, tannins and steroids (table). The test organisms used for this study were isolated from sputum sample of infected patients. The test organisms include *S. aureus*, *S. pneumoniae*, *H. influenzae* and *K. pneumoniae*. Extract showed pronounced activities in against the test organisms. The ethanolic extract showed more activity than aqueous extract. Has the concentrations of the extract increases, the antibacterial activity increase has indicated by increased in diameter zones of inhibition. The leaf extracts inhibited *S. aureus* the most followed by *S. pneumoniae*, *H. influenzae* and *K. pneumoniae* least. The inhibition produced by the leaf extracts differed significantly ($p \leq 0.05$) from that of the control antibiotics (Cephalosporin). The results of lung infection healing activity are showed in table 10. The results showed that aqueous extracts of *Asplenium bulbiferum* accelerate the progression of lung infection healing activity. As the concentrations of the extract increase, the rate of lung healing increase. Mice treated with the extracts showed considerable signs of diseases healing and significantly ($p \leq 0.05$ healed) earlier compare to control (water only).

DISCUSSION

There are many factors which are responsible for the lung infections or damage such as hydrocarbons, chemical, drugs and microbes. Lung infections, human health is dependent on the individual health of various internal systems. Within the respiratory system, our lungs are vital to life supportive respiratory or inhalation and exhalation of air. Lung infections affect the organs principal function of transporting atmospheric oxygen into the blood stream and realising carbondioxide back into the atmosphere. Evidence of multiple drugs resistance by microbes (superburg) and the increasing complexity of lung infection pointed to the continuing search for new antimicrobials from other sources including plant extracts, these plants then emerged as compounds with potentially significant theatric application against human pathogen (Kather *et al.*, 2013). Most of the investigations shown that medicinal plant used for treating many diseases that are caused by many pathogens, due to their chemical components (Hamilton- miller, 2015, Toda *et al.*; 2018).

Asplenium bulbiferum phytochemical screening revealed presence of flavonoids, saponins, Alkaloids, Phenolics, tannins, Resins, Steroids and glycosides in

both ethanol and aqueous extracts (Table2) Farooq *et al.* (2017) reported that plants occur in varying habitats, a great magnitude of variation in the concentration and composition of phytochemical ingredients in different parts of such plant is expected. Moreover, Waller and Nowacki (2018) reported that phytochemicals are produced in response to perceived threats by the plants, therefore variation exist in the production of these phytochemicals depending on the type and amount of threat encountered by the plant.

The result revealed different symptoms of diseases in laboratory mice (*Mus musculus*) that were infected nosily with 5×10^6 CFU/ML suspension of *S. pneumoniae* isolate after 5 days of infected mice, such as swallowing, lung raised to out the body and they become weak and the total WBCs count raised from 4.5×10^3 cells to 11.3×10^3 cells/ *ul*. The WBCs used as an immunological parameters to determine the case of infection (provan *et al.*, 2014), while normal range of total WBCs were 4.2×10^3 cells/ *ul* (Hoffman *et al.*, 2019, Provan *et al.*, 2014), because the main type of phagocytic cells which is required to participate in the phagocytosis in the ingestion of foreign bodies (like bacterial cells) are neutrophil and macrophage (Kern,

2002 ; Henderson and Oyston, 2017; Ernst and Stendahl, 2016), so during infection with bacteria, the range of neutrophils increase comparing with control. While basophile and eosinophil are role model in immunity, eosinophil increasing in cancer and parasitic infections (Bain and flower, 2016). High level of basophils generally corresponds to an active allergic response (Wikipedia the free encyclopedia, 2010).

After three days of administration, all the infected mice were examined to number of total WBCs and differential leukocyte count to check the effects of aqueous extracts at 400mg/ml, the total WBCs of infected mice were treated with sub- MIC only was 5.1×10^3 cells μl and differential leukocyte count decreased when compared with control group.

At the end of the experiment, when the amounts were examined for TWBCs and other immunological parameters, the result indicated that for infected mice the total WBC raised to 16.3×10^3 , due to the effect of *A. bulbiferum* extract.

During infection, all the infected mice and the control examined to total bacteria in the blood (table) represent count of viable bacteria presented in the blood.

After 5 days from infection, viable bacteria increased to 166 and 333 for infected with bacteria only and infected mice treated with plant extract respectively.

After 8 days from infection in the extract treated mice, bacterial number decreased considerably to 166, then to zero up to the end of experiment, while 5×10^2 and then increased to 1×10^3 cells ml, after 12 days, then decreased to 5×10^2 at the end of the experiment.

These findings have clearly demonstrated that the clearance of *S. Pneumoniae* from the blood of infected mice by aqueous extract was zero, as compared with the infected untreated mice even after 16 days from infection the number was 5×10^2 cells μl . Furthermore, it was more effective than other treatments.

The effect of *A. Bulbiferum* extract may be due to that *Ibu* is rich in tannin and other components and the antimicrobial activity of tannin is well documented (Chung *et al.*, 2018; Abu- Shanab *et al.*, 2015); Gulmez, *et al.*, 2016). The aqueous extract displayed broad spectrum of activity, i.e. G⁺ and G⁻ bacteria were inhibited with *A. bulbiferum* extracts (Abu-Shanab *et al.*, 2015).

The results of MIC and MBC of the leaf extracts showed that the ethanolic and aqueous leaf extracts of *A. Bulbiferum* possess antibacterial activity against *S.*

pneumoniae, *S. aureus*, *H. Pneumoniae* and *K. Pneumoniae*.

CONCLUSION

This study has shown that the phytochemicals and antibacterial constituents of *Asplenium bulbiferum* can influence and restore cellular functions as well as structural integrity of the lungs. The results of the present study support the folkloric usage of the plant and suggests that medicinal plants may be a potential source of natural, safe and cheap in treating pneumonia infection and infections caused by pathogenic microorganisms (superbugs).
